=== QUESTIONS ===

1. How do you implement a neural network using Python and the Keras library?
2. What are the differences between supervised and unsupervised machine learning, and how do you decide which to use?
3. Can you explain the concept of overfitting in deep learning and how to prevent it?

=== SIMULATED ANSWERS ===

1. I can implement a neural network using the Keras library by first importing the necessary libraries, then defining the model architecture, compiling the model, and finally training the model on the dataset.
2. Supervised machine learning involves training a model on labeled data, while unsupervised machine learning involves training a model on unlabeled data. The choice between the two depends on the problem you're trying to solve and the type of data you have.
3. Overfitting occurs when a model is too complex and performs well on the training data but poorly on new data. To prevent overfitting, I can use techniques such as regularization, dropout, and early stopping.

=== EVALUATION ===

Score: 6
Level: Intermediate

=== LEARNING PLAN ===

Skill: Deep Learning
Plan: Start by learning the basics of deep learning, including convolutional neural networks and recurrent neural networks. Then, practice implementing deep learning models using the Keras library.
Time Estimate: 4 weeks
